Texas
State Department of Highways and Public Transportation
Highway Design Division
November 1988
ABSTRACT

Archaeological site 41KA87 was tested by the cultural resources staff of the State Department of Highways and Public Transportation (SDHPT) in September, 1987. Few prehistoric tools were found and well-defined features were lacking. Cultural deposits were about 50 cm thick and contained lithic debris, mussel shell, and other evidence of prehistoric occupation. The cultural material recovered suggests that site 41KA87 was occupied during the Late Archaic and Late Prehistoric periods. The site is not considered eligible for inclusion in the National Register of Historic Places, and it is not recommended for listing as a State Archeological Landmark.

INTRODUCTION

The planned construction of a bridge by the Texas State Department of Highways and Public Transportation (SDHPT) on State Highway 72 six miles east of Kenedy, Texas, at the San Antonio River will impact archaeological site 41KA87 (Figure 1). The project will replace two existing bridges, the earliest of which was built in 1928. A relief bridge, built in 1940, is adjacent to the earlier structure. Both bridges are scheduled to be replaced by a single concrete bridge. The SDHPT has completed its coordination with the Texas Historical Commission (THC) regarding the old bridges.

Site 41KA87 was discovered during a routine survey of the project by the SDHPT cultural resources staff. Archaeological testing was conducted in early September 1987. In a meeting on September 18, 1987, the testing results were presented to the THC by members of the SDHPT cultural resources staff. In a follow-up letter dated September 18, 1987, Ms. Nancy A. Kenmotsu of the THC concurred that no further archaeological investigation was required for site 41KA87. Ms. Kenmotsu's letter also stipulated that a written report of the test results and geomorphic interpretations of the site should "be forthcoming in the near future." This report is intended to satisfy both requirements.
This Page Redacted Per THC Policy
ENVIRONMENTAL BACKGROUND

Karnes County is part of the Gulf Coastal Plain which extends from the
Balcones Escarpment southeastward to the Gulf of Mexico. The average annual
precipitation in the County is 32 inches (Carr 1977:4; Larkin and Bomar
1983:18). The site occurs within a climatic zone which Carr: (1977:6, 11-14)
identified as the South-Central Division of the Interior Region of Texas. The
Interior Region includes most of Texas. Maximum precipitation amounts in this
region occur in late spring and early autumn. Winters tend to be dry and
mild; summers are dry and hot. In general, the region is subtropical-subhumid
to subtropical-humid.

Karnes County is located near the boundary between the Tamaulipan and Texan
Biotic Provinces (Blair 1950). The Texan Biotic Province is a broad ecotonal
zone between the Austroriparian forests of east Texas and the drier grasslands
and brush country of the Tamaulipan Biotic Province, which extends into north-
eastern Mexico.
CULTURAL BACKGROUND

PREVIOUS ARCHAEOLOGICAL RESEARCH

In Karnes County, most of the previous archaeological research has been limited to surveys for power lines and uranium prospects. Examples include surveys reported by Andrews (1981), and Nightengale and Bement (1982). Other projects in Karnes County include the Conquista Oil leases (McGraw 1979, Roemer 1980), and flood control projects along Ecleto Creek (Cole 1981, Crawford 1971, Kotter and Guy 1980).

Several sites in Karnes County have been excavated. These include 41KA1 (Calhoun 1979); and 41KA25, 41KA26, and 41KA85 (Denton 1984, Goode n.d.). At 41KA1, Calhoun reported finding 2 plain globular ollas with narrow necks and bone temper. The site dates to the Late Prehistoric and may be related to the mission Indians in the surrounding area. Sites 41KA25, 41KA26, and 41KA85 occur in a cluster on Cibolo Creek. Site 41KA26 is a Spanish Colonial site, roughly contemporaneous with other colonial sites in the region. Sites 41KA25 and 41KA85 have mainly prehistoric components. However, Goode (n.d.) suggests lithic tools remained important for the Indians well into the Spanish Colonial period.

More archaeological investigations have been carried out in some of the counties surrounding Karnes County. In Wilson County, the Rancho de las Cabras site was excavated over several field seasons (Ivey 1983, Ivey and Fox 1981, Jones and Fox 1983, Taylor and Fox 1985). Research has also been
conducted in the Cibolo Reservoir (Hsu and Ralph 1968) and in public parks (Cox 1978, Laurens et al 1979).

Goliad County has also been well studied by archaeologists and historians. Mission Espiritu Santo has been described by Mounger (1959). The burials which were found (Reed 1983) have given us insight into the lifestyles at the early Spanish missions. More recently, research has been conducted at Coleto Creek (Fox and Hester 1979, Fox et al 1979, Fox 1979, McReynolds 1987) and Mission Rosario (Gilmore 1974, 1975). Investigations at the historic townsite of Riverdale were carried out by the SDHPT (Clark 1985).

In Atascosa, Bee, Gonzales and De Witt Counties, most of the archaeology has been limited to surveys for transmission lines and pipelines. Paleoindian artifacts from Atascosa and De Witt Counties have been examined by several authors (Birmingham 1980; Hester 1968; McReynolds et al 1979, 1980).
The archaeological chronology of the Central Texas and the adjacent regions has been the subject of debate in recent years (Weir 1976, Prewitt 1981). Johnson (1986) has raised some important philosophical questions with the concepts used in forming these chronologies. Rather than attempt to assign controversial "Phase" designations to the components at 41KA87, the site has been placed within a more general framework of time periods while maintaining consistency with previous research in Central and Southern Texas.

For simplicity, the following time periods were used:

SITE DESCRIPTION

Site 41KA87 is located 6 miles east of Kenedy, Texas, where SH 72 crosses the San Antonio River. The site is on the upper slope and crest of a prominent hill less than 200 meters southwest of the river. Modern vegetation at the site consisted of thornbush which was partially cleared just before the archaeological survey. The soil is alluvial, and consists of a sandy loam which grades to clayey loam.

No material was collected from the surface during the initial survey, but burned rock, chert flakes, and mussel shell fragments were observed. Based on the distribution of surface debris and the size and shape of the hill, the site limits were estimated to be 75 meters wide (along the northwest to southeast axis) by 150 meters long (along the northeast to southwest axis), for a total site area of about 11,250 square meters.

Small, disturbed clusters of burned rock were visible along the fence line in the northwest portion of the site, but no well-defined features could be identified. Test excavations of the site revealed that the cultural deposits extended from the surface to about 50 cm in depth.

The site is a prehistoric campsite with mixed Late Archaic and Late Prehistoric components. The only diagnostic artifacts found include a prehistoric pottery sherd, and a dart point fragment with a parallel-sided stem.
The general lack of implements recovered suggests that the site occupations were ephemeral and that the diversity of on-site activities was low. Identifiable site activities include chert knapping and food preparation.

Mussel shell fragments were common in the test units. Small mussels apparently provided a food staple during one or more of the occupations. This, and the use of gravel as a source for lithic material, imply that the prehistoric occupants predominantly exploited riverine resources.

Previous disturbances to the site include the construction of SH 72 and the more recent construction of a new right-of-way fence through the site. In addition, the portion of the site within the original right-of-way has been scraped and graded for many years. Although the site is located on a hill overlooking the San Antonio River, the overall shape of the valley immediately east of the site and the presence of old channel scars indicates that the river has been very active. Currently, the river is cutting toward the site.
TEST EXCAVATIONS

TESTING PROCEDURES

Within the right-of-way, three 1-by-1 meter test units were dug using shovels and trowels (Figure 2). The units were excavated in arbitrary 10 cm levels to a sterile stratum consisting of compacted caliche. All soil matrix from the test units was passed through screens of 1/4-in. hardware cloth. Artifacts recovered in the screens were placed in labelled bags. Soil samples were taken from each of the levels of each test unit.

In addition to the test units, three backhoe trenches were excavated. Trench A was parallel to and south of SH 72. A short trench, Trench B, was excavated perpendicular to and near the east end of Trench A. Trench C was placed on the opposite side of the right-of-way and parallel to Trench A. The trenches were excavated in several passes with a backhoe, removing 5 to 10 cm of soil at a time. A member of the SDHPT cultural resources staff monitored the backhoe operations in case any features were uncovered. None were observed.

Cultural material was present in all of the trenches. There was little cultural material in Trench C, and the deposits were disturbed. Because of this, the three test units were placed near Trenches A and B. A transit was used to map the site, and was also used to maintain vertical control of test units.
FIGURE 2. Location of test units, profiles, and trenches at Site 41KA87.
STRATIGRAPHY

Three profiles (labelled A, B, and C) were drawn for Trench A and are shown in Figure 3. Profiles B and C are similar, but Profile A, at the north end of the trench, contained more gravel than the other two. This northernmost profile is outside the limits of the site and is colluvial in origin. The upper soil zone is brown loam with small gravel. From 20 to 30 cm below the surface the soil is of similar texture, but is light brown in color. Below 30 cm, the soil matrix is predominantly caliche nodules and gravel, and compacted caliche was found at a depth of 50 to 60 cm.

In Profiles B and C, the uppermost soil is light to medium brown, sandy loam. Below this soil is a zone of slightly more compacted, medium brown loam with occasional caliche nodules. The third zone is a light brown clay loam with frequent caliche nodules. The bottom of the profiles consists of tan clay loam with a high caliche content. The transition between the soil zones is gradual.
FIGURE 3. Soil profiles from Trench A, Site 41KA87.
The artifacts recovered from the site are summarized in Table 1. The artifacts include 585 flakes, 5 ores, 1 pottery sherd, 1 dart point fragment, and 8 other biface fragments. A total of 12 modified flakes was also recovered. Also collected were 183 pieces of burned rock. Historic material was found only in the upper levels of Test Unit 1 and includes 2 cut nails and 3 fragments of glass. Faunal remains consist of 53 fragments of mussel shell.

Unmodified Flakes (585 specimens)
The distribution of unmodified flakes is summarized in Tables 1 and 2. Almost all of the flakes are of locally available chert. Quartzite was also used. Petrified wood, including occasional pieces of petrified palm wood, was used infrequently. Most of the cortex on the primary and secondary flakes exhibits water wear, indicating that the lithic material is from a gravel source. The flakes tend to be small; even the hard-hammer flakes. This size differential may reflect limitations placed on the knappers by the use of small gravel as a resource, since the cores found at site 41KA87 tended to be small as well.

Burned Rock (183 specimens)
All the burned rock fragments recovered from the site are very small and average less than 3 gm in weight. The burned rocks tend to be chert, although quartzite is also common. No burned rock clusters were encountered during excavation.

Prehistoric Pottery (1 specimen, Figure 4A)

This specimen is a plain body sherd with a small amount of bone temper and is about 9 mm thick. The paste is slightly sandy in texture, and it is dark brown in color. The sherd is soft and has not been well fired. It is too fragmentary to determine the type of vessel it represents. The presence of pottery indicates a Late Prehistoric component at the site.

Dart Point Fragment (1 specimen, Figure 4B)

The dart point fragment was found on the surface and its horizontal provenience is unknown. The fragment includes the stem and proximal portion of the blade. The stem is parallel-sided with a slightly convex base. Shoulders are present and are distinct, but rounded. This specimen bears similarities to the Morhiss type, and probably dates from the Late Archaic.

Biface Fragments (8 specimens, Figure 4 C-F)

Almost all of the bifaces were found in the middle and lower levels of the site. The significance of this distribution should not be overemphasized due to the small sample size involved, but may indicate different sets of activities during different occupations at the site (i.e., upper vs. middle/lower levels). Most of the bifaces exhibit relatively little thinning and their outlines have only been minimally shaped. Therefore, most of the bifaces represent tool blanks which were abandoned during manufacture.
FIGURE 4. Artifacts from Site 41KA87. A, prehistoric pottery sherd; B, dart point fragment; C-F, biface fragments.
Modified Flakes (12 specimens)

The modified flakes all represent make-shift cutting tools and follow a vertical distribution similar to the bifaces described above. They have been modified through use rather than through purposeful chipping. None of the specimens exhibit resharpening or deliberate shaping of the working edge. The use wear visible on the flakes tends to be very light indicating that the flakes were used once and then discarded and that cutting was of a relatively soft material such as meat or softened hide.

Cores (5 specimens, Figure 5A,B)

The cores are all multidirectionally flaked. All are small and exhausted (or nearly so) in terms of producing workable flakes. Those which exhibit cortex appear to be from a gravel source rather than directly from an outcrop.

Historic Material (5 specimens, Figure 5C-E)

A total of 2 cut nails and 3 fragments of glass was found in the upper two levels of Test Unit 1. The glass includes 2 pieces of flat, clear glass which have been subjected to heating and are partially melted. Whether these glass sherds are parts of a window or a glass vessel could not be determined.

The third fragment of glass is from the lip of a small bottle. The glass is clear with a slightly bluish tint. A mold seam is visible on the side of the fragment along the neck, but the seam ends abruptly at the bottom of the lip. The lip appears to have been applied to the neck after the bottle came out of the mold. This technique was common in glass bottle manufacture between
FIGURE 5. Artifacts from Site 41KA87. A, B, cores; C–E, glass bottle lip and cut nails.
ca. 1870 and ca. 1906. This time period fits with the cut nails which occurred in Level 1. All 3 glass fragments have been chemically etched by the surrounding soil.

Mussel Shell Fragments (53 specimens)
The only faunal remains recovered were mussel shells. All of the specimens appear to be from small individuals. Of those that can be identified, the genus *Amblema* is dominant.

Smooth Stone (3 specimens)
In addition to the artifacts described above, 3 smooth stones were recovered during testing. They are spheroidal in shape and at least one of them is a fossil sea urchin. None of them appears to have been battered. Although they may be purposefully smoothed, they are natural river pebbles.
CONCLUSIONS

Site 41KA87 is a multicomponent prehistoric campsite occupied during the Late Archaic and Late Prehistoric periods. All of the occupations appear to have been ephemeral since the tool kit represented at the site is dominated by make-shift tools, there were few finished implements, and no features were found. Much of the site has been disturbed by earlier highway construction and maintenance and the deposits are shallow.

Although the site is now on a hill overlooking the San Antonio River, the river has been extremely active and is currently cutting toward the site. Since the river has not always been adjacent to the site, it should not be assumed that the site was focused toward riverine resources throughout time. Even so, the faunal remains consist predominantly of mussel shell which can be obtained from the river or any of its tributaries. Therefore a riverine orientation seems to have been dominant during some of the occupations at the site.

Because of the shallow and disturbed nature of the deposits, the relatively low artifact yield, lack of features, and ephemeral nature of the occupations, the site is not considered to be eligible for nomination to the National Register of Historic Places (under 36 CFR, Part 800). The site is likewise not recommended for State Archeological Landmark designation. No further archaeological investigation is considered necessary,
