# TEXAS FORESTRY PAPER

No. 28

May, 1976

## SCHOOL OF FORESTRY STEPHEN F. AUSTIN STATE UNIVERSITY

Nacogdoches, Texas

### PLANTS FOLLOWING TIMBER HARVEST: IMPORTANCE TO SONGBIRDS

*J. J. Stransky, L. K. Halls,  
and  
E. S. Nixon<sup>1</sup>*

Of 35 plant species or groups important as food for songbirds, 28 were more abundant on a clear-cut area than in adjacent pine forest 15 months after a timber harvest. This is an important early finding of a continuing wildlife food study on East Texas upland forests being regenerated by site preparation and planting after clearcutting.

#### METHODS

The study site was about 24 km (15 miles) south of Nacogdoches, Texas, in a forest dominated by loblolly (*Pinus taeda* L.) and shortleaf pine (*P. echinata* Mill.) interspersed with sweetgum (*Liquidambar styraciflua* L.), blackgum (*Nyssa sylvatica* Marsh.), and several species of oaks (*Quercus* spp.).

In May 1970, all trees except a few scattered oaks and gums were cleared from a strip 443 m (1453.4 feet) long and 137 m (449.5 feet) wide; approximately 6.0 hectares (15 acres). Logging slash, understory shrubs and vines, and herbaceous vegetation were cut with a Marden brush chopper and burned in the winter of 1970 - 71. The area was planted to loblolly pine seedlings in late February and early March 1971. The understory of the adjacent uncut forest was burned in February of the same year.

In March, vegetation sampling plots were established on 21 randomly chosen transects across the clearcut strip paralleling its short axis and extending into the adjacent forest. Six sampling points were located along each transect, three in the woods and three in the open, at 10, 30, and 50m from the forest edge (32, 98, and 164 feet respectively).

---

<sup>1</sup>Stransky and Halls are on the staff of the Wildlife Habitat and Silviculture Laboratory, which is maintained at Nacogdoches, Texas 75961, by the Southern Forest Experiment Station, USDA Forest Service, in cooperation with the School of Forestry, Stephen F. Austin State University. Nixon is with the Department of Biology, Stephen F. Austin State University, Nacogdoches, Texas 75961.

At each sampling point, herbaceous vegetation was tallied on 1 m<sup>2</sup> (10.7 ft<sup>2</sup>) plots in March, April, May, June, August, September and October of 1971. Woody plants were counted in August on 4 m<sup>2</sup> (43 ft<sup>2</sup>) plots, centered at the same points.

Density per plot and frequency of distribution were calculated for each species:

$$\text{Density per plot} = \frac{\text{Number of individuals of the species}}{\text{Number of plots}}$$

$$\text{Frequency of Distribution (\%)} = \frac{\text{Number of plots on which species occurs}}{\text{Total plots sampled}} \times 100$$

Use of plant species by songbirds was evaluated as reported by Martin, Zim, and Nelson (1951).

## RESULTS AND DISCUSSION

By the end of the first growing season, natural reseeding and sprouting had completely revegetated the clearcut area. Herbaceous species were most abundant in the open; 68% were recorded only on plots in the cutover area. The majority of the woody species (76.8%) occurred both in the open and in the woods.

A total of 105 herbaceous species was recorded, including 25 grasses (Gramineae), 24 composites (Compositae), and 13 legumes (Leguminosae) (Table 1). Among the 56 woody species there were 6 oaks, 5 greenbriars (*Smilax* spp.), 5 members of the rose family (Rosaceae), 4 of the grape family (Vitaceae), and 3 sumacs (*Rhus* spp.) (Stransky et al., 1974) (Table 2). In both tables, species and species groups reported by Martin, Zim and Nelson (1951) to provide food for one or more songbird species are followed by asterisks. Many of the other species are probably consumed, but were not identified in available reports. Thus most of the grasses, sunflowers and smaller-seeded legumes probably constitute important food resources for many of these bird species.

The most frequently occurring songbird food plants included wood-sorrel (*Oxalis dillenii* Jacq.), three-seeded mercury (*Acalypha* spp.), shining sumac (*Rhus copallina* L.), blackberry (*Rubus* spp.), Virginia creeper (*Parthenocissus quinquefolia* (L.) Planch.), panic grasses (*Panicum* spp.), ragweed (*Ambrosia artemisiifolia* L.), poison ivy (*Rhus toxicodendron* L.), greenbriars (*Smilax* spp.), and sassafras (*Sassafras albidum* (Nutt.) Nees.). All except the last three were more plentiful in the open than in the woods. In Table 3, eight of these species are rated according to their importance for songbirds that were frequently sighted on this area before timber cutting (Michael and Thornburgh, 1971). The seasonal occurrence of the birds is coded according to Fisher<sup>2</sup>.

---

<sup>2</sup>Fisher, C. D. 1974. Preliminary Checklist of the Birds of the Pineywoods Region of East Texas. Stephen F. Austin State University, Department of Biology. 3 pp. Mimeo.

In addition to the birds listed in Table 3, we observed the Ruby-Throated Hummingbird (*Archilochus colubris*). It feeds on flowers of Japanese honeysuckle (*Lonicera japonica* Thunb.), thistle (*Cirsium* spp.), beebalm (*Monarda punctata* L.), verbain (*Verbena halei* Small), and evening primroses (*Oenothera* spp.), all of which grew on the open area.

Other plant species producing food for small seed-eating birds found on the cleared area included sedges (Cyperaceae), rushes (Juncaceae), spurges (Euphorbiaceae), wild geranium (*Geranium carolinianum* L.), plantain (*Plantago virginica* L.), peppervine (*Ampelopsis arborea* (L.) Koehne), American beautyberry (*Callicarpa americana* L.), American holly (*Ilex opaca* Ait.), red mulberry (*Morus rubra* L.), and common persimmon (*Diospyros virginiana* L.), nightshades (Solanaceae), violet (*Viola septemloba* Le Conte), grapes (*Vitis* spp.), rusty blackhaw (*Viburnum rufidulum* Raf.), and flowering dogwood (*Cornus florida* L.).

The seasonal peaks in fruiting and seed maturity were distributed over the year so that some kind of food was always available. Seed from late summer- and fall-maturing grapes, greenbriars, sassafras, honeysuckle, Virginia creeper, American beautyberry, peppervine, sumac, poison ivy, ragweed, dovewood (*Croton capitatus* Michx.), and legumes furnished overwintering food. Fruiting plantain, woodsorrel, panic grasses, sedges, haw, and blackberry provided food in spring and early summer. Grapes, plums, grasses, and a variety of seed-bearing herbaceous plants were available in late summer and early fall to complete the annual cycle of food production.

This early successional stage immediately after cutting is favorable to seed-eating songbirds, but normally lasts only 4 to 8 years, depending on pine seedling spacing and site quality. Additional nearby cuttings are desirable to afford continuing food supplies before the developing pines shade out the light-demanding herbaceous species.

Plant succession on this study area will be observed for 10 years to quantify the effect of planted pines on wildlife food plant availability.
