SECTION 1. REPORT

1.1 Introduction. East Texas has predominantly been categorized historically as a forestry and timber management region. The nearest region to expectedly encounter viewing a large number of properties containing the growth of nut-bearing tree plantations, better known as orchards, is the Hill Country or South Texas Regions. During 2012, I witnessed a rural real estate transaction between an East Texas timber landowner and successful almond orchard farmer. The almond farmer had no previous experience with the practice and management of Texas loblolly pine plantations; however, he had interest in diversifying his real estate investment portfolio to include a pine plantation offering a different soil type than he was used to cultivating for his almond farms. The more than two-thousand acre Neches River property of his choice, was in fact a practical timberland investment, with a desirable projected return-on-investment. As a result, the almond farmer can now learn the principles associated with growing, managing, and harvesting pine timber in East Texas, in addition to examining the new soil type and preparing it for his experimental East Texas almond orchard farm. Due to the almond farmers unorthodox endeavor, the experience enlightened me and generated the basis of the following study; does the East Texas region host lands that are practical, or even potentially possible, to develop large acreage into nut-bearing orchards.

1.2 Scope. This feasibility study was conceived outside the range of numerous suggested geographical information systems natural resources management plans and assessments. The parameters for this study required specifying an Area-of-Interest (AOI) no less than 4,000 acres from within a much larger 40,700 acre designated area of the Davy Crockett National Forest, in Houston County, Texas. The requirements additionally declare that I must generate, at minimum, eight maps derived by utilizing the GIS tools and procedures learned during the GIS 390 course. These procedures and maps are expected to accompany the report and validate the methods executed during the research.

1.3 Background Theory. This study was conducted with the expectation that the criteria selection of the subject, workflow, and GIS analysis, can, and will undoubtedly offer a reliable form of land-use determination techniques during future accounts of due-diligence. In this particular study I arranged for the investigation to include the likelihood of a pecan orchard, as opposed to the previously mentioned topic of almond orchards, primarily because of an already existing pecan orchard within the vicinity of the study area. Coincidently, the two-thousand acre Neches River property purchased by the almond farmer, just happens to be minutes away from the study area. In coordination with the nearby existing pecan orchard, the 4,000 acre AOI was established upon analyzing the area for the most attractive creeks, streams, and road system infrastructure available, to initially support the reality of a potential pecan orchard. In this study, the AOI is referred to as the Hickory Creek area due to the predominant and geographically balanced water features in the study area. The objective for this study is to use available data, scientific facts, and the most foundational principles of geospatial analysis in natural resources, to determine if a pecan orchard is suitable for the selected study area based on soil type. Additionally, the end goal is reduce the AOI down to a focused area, as small as 10%, in order to precisely identify the most desirable tracts of land in the study area, with consideration given to existing county tax parcel ownership data.
Map 1 Summary. Proximity of Feasibility Study. Map 1 was the first map generated during this study and established the genre for the layout for the maps that follow map 1. The primary features in this map include the location for the existing pecan orchard, all of the owners’ real properties in Houston County, the surrounding Davy Crockett National Forest, and the proposed orchard study area. This map was presented first so that the audience can gain a clear understanding of where the remainder of the study will take place.

Map 2 Summary. Digital Ortho-Quarter Quadrangle (DOQQ). This map represents the specified location of the pecan orchard feasibility study and research area in the vicinity of Hickory Creek. The basemap imagery data underlying the study area was provided by the Texas Natural Resources Information System and was captured during 2012. This map also offers a great view of some of the road systems, creeks, and branches that will factor into the search for the most suitable orchard area.

Map 3 Summary. Digital Raster Graphics (DRG). Map 3 also represents the specified location of the pecan orchard feasibility study and research area in the vicinity of Hickory Creek. The 7.5 x 7.5 minute basemap imagery underlying the study area was georeferenced to the surface of the earth and fit to the Universal Transverse Mercator projection by the USGS. In this map, the imagery was provided by the Texas Natural Resources Information System. This map offers an aid in understanding the terrain in the Hickory Creek area and added topographical support during the evaluation process.
Pecan Orchard Feasibility Study
Map 1. Proximity of Feasibility Study

This map represents the specified location of the pecan orchard feasibility study and research area in the vicinity of Hickory Creek located in Houston, County, Texas. The primary map features include an existing pecan orchard, all of the owner’s lands, the surrounding Davy Crockett National Forest, and the proposed orchard study area.

SECTION 2. ANALYSIS

2.1 Phase I. Incorporating Soil Type Data. Choosing the location for a new pecan orchard should be a thorough process, because it can become very costly to a pecan farmer or investor if the orchard is developed within the wrong climate, soils, water resources, and numerous other factors.

The first question composed during this study was, should additional pecan orchards be established in the Hickory Creek area of the Davy Crockett National Forest? In order to validate the question, it was first necessary to identify the most common factor resulting in mortality among pecan tree orchards, in general. Evidence from research of failed pecan orchards reveals that the largest contributing factor to pecan orchard mortality is poor soil. Therefore, this phase of research was designed to use ArcMap to import existing soil data shapefiles into the AOI, as well as the existing pecan orchard.

The nearby existing pecan orchard age is unknown, but believed to be less than ten years old. The orchard contains 106 acres of planted trees that lays 3.4 miles to the southeast of the Hickory Creek study area, on U.S. Highway 7, adjoining the city limits of Kennard, Texas. By examining the soil types of the existing pecan orchard, this offered an easy comparison of soil in the area which has proven to offer a dependable growing environment for pecan trees.

The soil type data for this study was provided by the [1] U.S. Department of Agriculture Natural Resources Conservation Service Soil Survey for Houston County, Texas. Listed below are the soil types that remain in the two emphasized areas of the investigation, after the analysis had been conducted during this phase.

Hickory Creek Study Area Soil Types:

- AaB - Alazan very fine sandy loam
- AtB - Attoyac fine sandy loam
- AuD - Austonio fine sandy loam
- BaB - Bernaldo fine sandy loam
- BeA - Besner fine sandy loam
- BwB - Bowie fine sandy loam
- CtE - Cuthbert fine sandy loam
- HaA - Hainesville fine sand
- Iu - Iulus fine sandy loam
- KfC - Kirvin fine sandy loam
- KhC - KhC—Kirvin soils
- KuB - Kurth fine sandy loam

Existing Pecan Orchard Soil Types:

- BaB - Bernaldo fine sandy loam
- HaA - Hainesville fine sand
- KuB - Kurth fine sandy loam
- Kp – Koury silt loam

- LaE - LaCerda clay loam
- Lc - Laneville loam
- LtC - Lilbert loamy fine sand
- MoA - Mollville loam
- MpA - Mollville-Besner complex
- Oz - Ozias-Pophers complex
- SwA - Sawlit-Latex complex
- TaE - Tenaha loamy fine sand
- WnB - Woden fine sandy loam
- WoB - Woodtell very fine sandy loam
- WoE - Woodtell very fine sandy loam
- KuD - Kurth fine sandy loam
- MxA – Moten-Multey complex
- Po – Pophers silt loam
**Map 4 Summary. Hickory Creek Study Area Soil Survey.** The analysis truly takes an informative step with Map 4. The soil survey data was imported into ArcMap, followed by initiating the clip tool in order to retain the soil data for the Hickory Creek AOI only. The map collages all of the soil types in the AOI that must be evaluated in order to determine if a pecan orchard will be feasible. The symbology for each soil type is represented by its own unique semi-transparent color, offering ease in distinguishing where each soil type area exists. The map also contains the 2012 digital ortho-quarter quadrangle satellite imagery basemap, road systems, creeks, and branches.

**Map 5 Summary. Existing Pecan Orchard Soil Survey.** Map 5 extended the range of soil types that may be included during this phase of the study. Like the Hickory Creek AOI soil data in map 4, the soil survey data for the existing pecan orchard was imported into ArcMap, followed by initiating the clip tool in order to retain the soil data for that area only. This map also contains similar symbology for each soil type that is represented by its own unique semi-transparent color. Despite not being a necessity, the map also contains the 2012 digital ortho-quarter quadrangle satellite imagery basemap, road systems, creeks, and branches, in order to maintain consistency among the maps during the study.

2.2 Phase II. Evaluating Common Soils. The next phase involved analyzing which soil types that the Hickory Creek study area, and the existing pecan orchard have in common. As mentioned during phase one, by identifying the soil types of the existing pecan orchard, the study can establish a basis for comparison between the Hickory Creek AOI and an area in which the soils have proven to effectively grow pecan trees.

Using ArcMap, tabular analysis confirmed that the existing pecan orchard has a total of nine acres in common with 480 acres of the Hickory Creek study area soil types. This reveals a ratio of 1:53, or it can be better illustrated by stating that there are approximately fifty-three acres compatible with the existing orchard soil type, for every nine acres in the Hickory Creek study area. Performing the analysis deduced that the following soil types were determined to share commonality between the Hickory Creek study area and the existing pecan orchard:

- BaB - Bernaldo fine sandy loam
- KuB - Kurth fine sandy loam
- HaA - Hainesville fine sand

Non-Forest Areas. After identifying the common soil types between the two areas, the 2012 digital ortho-quarter quadrangle satellite imagery was then used to construct new polygon shapefiles of the non-forest areas in the Hickory Creek area. The purpose of identifying these regions was to designate which properties contain vacant agricultural land that may currently embrace an orchard site, without having to suffer the loss of existing timber and land-use conversion costs.

The non-forest land polygons were then overlayed with the soil types derived during the first stage of phase two, in order to taper further into strategically selecting prime locations for the potential orchard. The last step of this phase was to execute the intersect tool leaving only the Hickory Creek AOI with non-forest properties that are compatible with the soil types of the existing pecan orchard.

Map 6 Summary. Map 6 illustrates the soil types in the Hickory Creek study area that coincide with the existing pecan orchard. Tabular analysis was used in ArcMap to generate the selection, followed by exporting the selection to a new data shapefile. The analysis revealed that there are 480.33 acres of common soil types shared with the soils underlying the nearby existing pecan orchard. Once again, this map carries the layout trend with the unique semi-transparent soil type symbology, 2012 digital ortho-quarter quadrangle satellite imagery basemap, road systems, creeks, and branches.

Map 7 Summary. This map continues the layout feature scheme used in the previous map. Map 7, however, reveals the soil types of the nearby existing pecan orchard that were derived during the first stage of the phase two analysis, showing only those types which are in common with the Hickory Creek study area soils. The map illustrates that 9.08 acres of soil types were derived from the analysis that correlate with soils from the Hickory Creek area.
Map 8 Summary. Hickory Creek Non-Forested Areas Overlying Digital Ortho-Quarter Quadrangle. This map is another segment of the continued analytical process towards the path of identifying a specific property. Map 8 also continues the layout feature scheme used in the previous map. The results demonstrated in this map display 1,351.81 acres of agricultural land that will potentially accommodate a pecan orchard without having to harvest existing timber and encounter dramatic land-use conversion costs.

Map 9 Summary. Hickory Creek Non-Forested Areas Overlying Digital Raster Graphics. This map offers an alternative underlying basemap for the previous mapping results, displaying the newly digitized 1,351.81 acres of agricultural land over the 7.5 x 7.5 minute USGS topographic basemap that were obtained from the Texas Natural Resources Information System.

Map 10 Summary. Hickory Creek Non-Forested Areas Overlying Soil Survey. This map enters the next stage of analysis by combining the entire study area soil survey with the 1,351.81 acres of non-forested polygons. This segment of the data analysis simply offers an opportunity to witness the complete dataset prior to executing the tools during the next stage of the analysis. Map 10 blends the semi-transparent symbology from the soil survey with opaque yellow polygons representing the agricultural land areas, both laying above the 2012 digital ortho-quarter quadrangle satellite imagery basemap, road systems, creeks, and branches.

Map 11 Summary. Hickory Creek Non-Forested Areas and Soil Types in Common with Existing Pecan Orchard. Map 11 minimizes the soil survey data once again to display only the soils that the Hickory Creek AOI have in common with the existing pecan orchard. Additionally, the map inverts the symbology for the 1,351.81 acres of non-forested polygons by illustrating them as a yellow polyline only. As a visual measure, a semi-transparent feature is added and clipped to the study area perimeter that creates a dark opaque coat over all of the forested areas that will be less of an emphasis from this point of the study and forward.

Map 12 Summary. Hickory Creek Intersect of Non-Forested Areas and Soil Types in Common with Existing Pecan Orchard. In generating this map, the intersect geoprocessing tool was performed in this portion of the analysis in order to reveal the most highly preferred common soil types shared with the soils underlying the nearby existing pecan orchard. Map 12 concludes the analysis for phase two of the study and emphasizes 177.38 acres of compliant non-forested soil types that will continue to be considered as probable for a potential pecan orchard during the remainder of the study.

2.3 Phase III. Identifying USDA Recommendations. This phase of the study focuses on next evaluating the soil data for the Hickory Creek AOI by acknowledging the recommendations made by the [1] *U.S. Department of Agriculture Natural Resources Conservation Service Soil Survey for Houston County, Texas.*

Some of the soil characteristics needed for pecan trees that were considered, and regarded as critical during this phase of the analysis, include:

- Deep alluvial soils along rivers and streams; suggested 36” of aerable soil.
- The soil should have the ability to hold large quantities of water; a permeable clayey subsoil can aid in water holding capacity without waterlogging the rooting zone.
- The water table should remain at least 6 feet below the soil surface during wet periods. Shallow water tables limit rooting zones, which in turn limit available water during prolonged droughts.
- The terrain should be level or gently sloping and free of areas that hold water.
- During the fall, long-term flooding lands can wash the pecan crop downstream.
- An area prone to frequent and long-term flooding should not be considered.
- Level or gentle slopes help in air drainage.
- Alluvial soils are preferred, but uplands with deep well-drained soils and proper managing can also be productive.
- Surface drainage.
- No long-term flooding; fall floods can wash the pecan crop downstream or make inaccessible for harvest. April to June flooding can reduce production levels.

The Soil Survey of Houston County, Texas, provided by the U.S. Department of Agriculture Natural Resources Conservation Service offers details for most of the previously noted characteristics of the soils in the study area, and advises that the following soil types are recommended for orchards. Fine sandy loam soils, such as, Alto, Attoyac, Austonio, Bowie, Kirvin, and Woden; as well as, loamy fine sand soils such as, Lilbert and Teneha. After careful review of the USDA recommendations, the following soil types in the Hickory Creek study area were determined to meet the conditions of the criteria for a desirable pecan orchard development:

- AtB - Attoyac fine sandy loam
- AuD - Austonio fine sandy loam
- BwB - Bowie fine sandy loam
- KfC - Kirvin fine sandy loam
- LtC - Lilbert loamy fine sand
- TaE - Tenaha loamy fine sand
- WnB - Woden fine sandy loam

The spatial processing of the soil types recommended by the USDA Houston County Soil Survey were conducted in the same manner as phase two. Phase two was finalized by narrowing down the soil types shared from those underlying the nearby existing pecan orchard, resulting in 177.38 acres of potential pecan orchard land. After identifying the non-forested USDA compliant soil types during this phase of the study, the merge tool was then used to combine the soil data derived from phase two with the soil data apprehended from phase three. After the data merge, the recently combined Hickory Creek phase two and three suitable soil sites are once again condensed. The reduction was based on a visual selection.
of the soil polygons contiguousness, in combination with attractions from nearby creek, stream, and road infrastructure.

**Map 13 Summary. Hickory Creek Non-forested Areas and USDA Recommended Soil Types.** Map 13 initiates the first step of analysis during phase three of the study, similar to the process undertaken while creating map 11 during phase two. This map includes 1,086 acres of soil types that are recommended by the USDA for an orchard in Houston County, Texas are illustrated in this map, in addition to the 1,351.81 acres of non-forested polygons in the Hickory Creek study area. Once again the non-forested areas are represented by a yellow polyline, with the dark opaque feature coating all of the forested areas in the study area.

**Map 14 Summary. Hickory Creek Intersect of Non-forested Areas and USDA Recommended Soil Types.** In generating this map, the intersect geoprocessing tool was performed, discarding the unneeded soil locations and non-forested areas. In return this process revealed an area of 261.31 acres of highly preferred soil types with consideration given to the recommendations made by the U.S. Department of Agriculture Natural Resources Conservation Service Soil Survey for Houston County, Texas. Map 14 sets the stage for phase three or the soil survey analysis, by preparing for the joining of the recommended USDA soil types output, with the preferred soils generated during phase two of the assessment.

**Map 15 Summary. Hickory Creek Merge of Non-forested Areas with Compliant USDA Recommended and Existing Pecan Orchard Soil Types.** The final output from phase three is represented with map 15. In this map, USDA recommended soil types for an orchard in Houston County, and the soil types in common with the nearby existing pecan orchard were combined by executing the merge tool in ArcMap. The result returned a combined total of 438.69 acres of highly desirable soil types that would present a suitable location for a Hickory Creek pecan orchard development. The area that offers the greatest level of obvious appeal is represented in map 15 with a red dashed ellipse around the region. During the final analysis in phase four of this study, the red dashed region represents the main area of focus where the soil types were cross-referenced with the parcel data.
Pecan Orchard Feasibility Study
Map 13. Hickory Creek Non-forested Areas and USDA Recommended Soil Types

2.4 Phase IV. Land Parcel Analysis. The final phase of this study required performing an analysis by overlaying Houston County land ownership parcel data over the study area and selecting the tracts that offer the most evident resources parallel with the criteria of this entire study. The analysis performed during phase three prepared the soil polygons to be integrated with the land parcel data. The Houston County land ownership parcel data was obtained from OGinfo, which is a petroleum industry supplier of various data. Of Phase four of the study results in the identification of 759.75 acres of private agricultural land, classified as real property. These tracts include exactly 250.18 acres of the 438.69 acres of desirable soils derived in the previous phases of this study. In contrast, 33% of the selected tracts of land contain the desirable soil types.

By furthering the geoprocessing abilities of ArcMap even further, the union tool was executed with the parcel boundaries and the desirable soil types. This divided each soil polygon along the perimeter of each parcel boundary, enabling to evaluate the potential amount of soils within each parcel. Some of the tracts only contain a small amount of usable soil for an orchard, however, several of the tracts consist of more than 30% of the desirable soil type within that parcel alone.

Map 16 Summary. Hickory Creek Compliant Soil Types and Land Parcel Analysis. The final official study map continues with the layout trend of the unique semi-transparent soil type symbology for each soil type, 2012 digital ortho-quarter quadrangle satellite imagery basemap, road systems, creeks, and branches. The dark opaque feature within the study area that surrounds the final selection of land parcels denotes all of the areas which are not of interest in this study. Map 16 also includes 250.18 acres of the soil types derived from phases two and three of this study. All of the Houston County parcels within the study area that are not of interest for the pecan orchard location are illustrated with white polylines. Finally, the map illustrates the most highly desirable and feasible properties for the Hickory Creek Pecan Orchard indicated by thick red polylines.

This map represents the specified location of the pecan orchard feasibility study and research area in the vicinity of Hickory Creek located in Houston, County, Texas. This map shows the soil types that are recommended by the USDA for planting pecan trees, along with soil types that are in common with the existing pecan orchard. The map is overlayed with parcel data, of which the most appropriate tracts have been selected for the proposed Hickory Creek Pecan Orchard.

2.5 Additional Maps.

Map 17 Summary. Hickory Creek Aspect Calculation. An aspect calculation was performed for the Hickory Creek study area. The aspect tool calculates the direction in which the plane fitted to the slope faces for each cell to its neighbors in the region.

Map 18 Summary. Hickory Creek Slope Calculation. A slope calculation was performed and identifies the slope (gradient, or rate of maximum change in z-value) from each cell of the raster surface digital elevation model.

Map 19 Summary. Hickory Creek Digital Elevation Model (DEM). Map 19 was generated from data provided by the Texas Natural Resources Information System. The map illustrates the terrain as a continuous surface raster image in the form of a digital elevation model (DEM).

Map 20 Summary. Hickory Creek IDW Interpolation Analysis. This map was derived by interpolation of an elevation point dataset provided by the Texas Natural Resources Information System, calculating the inverse distance weighted (IDW) technique.

Map 21 Summary. Hickory Creek Triangulated Irregular Network with Edges. This map illustrates a triangulated irregular network (TIN) with edges, which is a digital data structure used to represent the terrain in a vector based surface.

Map 22 Summary. Hickory Creek Triangulated Irregular Network with Contours. Map 22 illustrates an alternative version of a triangulated irregular network by displaying the vector based surface in addition to contour lines.

SECTION 3. RESULTS

3.1 Concerns. Some of the issues that were experienced during the project, include:

- There was limitation in generating a consistent symbology for the soil types throughout the study. The reason appeared to be related to an issue between files containing non-congruent table data having the capability of utilizing the same symbology. Upon importing the layer file that had been generated after setting up the soils symbology, the symbology import in the layer settings window would eliminate some of the tabular data after applying the actions.
- The soil type’s legend mysteriously erased several times when trying to finalize map layouts, specifically when moving and resizing using the align-center function for the two legends.
- Some of the geoprocessing tools would not function on the first request, such as clip or intersect, but saving the file and restarting it on each of the encounters allowed them to run effectively on the next startup.
- Creating a custom shapefile locator map to clip to in the map layout has limitations. The standard data frame allows the user to pan or zoom in the data frame window, in order to adjust the data view area in the selected frame, while still in layout view. Unfortunately, the data frame will not update appropriately and will display a new unwanted shape from the data view pan and the user must undo the changes.

3.2 Conclusion. The Hickory Creek pecan orchard feasibility study did effectively meet the overall objective for the assessment. The characteristics used to initially qualify the AOI were appropriate and appear to have contributed to the success of the investigation. In addition to the selected natural resource features and road systems, having the nearby existing pecan orchard in Kennard provided a great opportunity for selecting and comparing soil types. By merging the USDA NRCS Soil Survey of Houston County recommended soil types with the soils in common with the nearby orchard, it conveyed an excellent concentration for the parcel selection needed in order to determine where to purchase property. Based on the results from this study, with an emphasis on soil types, there is an evident opportunity for the parcels validated in Map 16 to offer a favorable site for the development of a pecan orchard in the Hickory Creek area.

The results from this study have validated that implementing the appropriate workflow strategies during GIS analysis can tremendously benefit the due-diligence process while examining land-use in regard to natural resources. The almond farmer described during the introduction that purchased the two-thousand acre Neches River timber land property, can currently manage his pine plantations and eventually convert the land into an orchard. However, despite East Texas consisting largely of yellow pine timber, land owners in the East Texas Region can currently develop pecan orchards on their agricultural or non-forested land, by examining their property with the analysis methods that performed during this study.
